Abstract

Although, in theory, a considerable amount of literature emphasizes the significance of employee incentive pay, there is not much empirical research indicating their dispersion in practice. The primary purpose of this study is to explore the level of implementation of various incentives in three countries: Slovenia, Serbia, Bosnia and Herzegovina. The research was conducted on a sample of 321 companies. Data for this study were extracted from the CRANET dataset. The latest data collection cycle was conducted in 2021-2022. In addition to descriptive statistics, the Pearson Chi-Square Test and Cramer's V test were used to test hypotheses. The research results indicate a statistically significant difference in using most observed compensation elements among the observed countries. The study contributes to compensation management literature by presenting empirical data regarding the degree of implementation of various compensation instruments in three observed countries.

Introduction

Compensation or rewards include various elements of material and non-material nature that employees receive for their work. Given that the amount and the structure of total rewards directly influence the attitudes and behaviour of employees, it is in the interest of every employer to use reward systems as a tool to achieve organizational business goals. Academics would argue that rewarding employees is one of human resource management's most important activities (HRM) activities.

Numerous studies conducted in the last two or three decades confirm the multiple significance of incentive reward systems. Compensation is essential in attracting potential employees and maintaining high performance and work motivation (Fay & Thompson, 2001). Additionally, compensations affect employee satisfaction (Siems et al., 2012; Mudor & Tooksoon, 2011; Judge et al., 2010), organizational behaviour (Gupta & Shaw, 2014), and organizational performance (Chen

* Corresponding author.

& Huang, 2009; Subramony, 2009; Gooderham et al., 2008).

Contemporary organizations recognize that a more complex reward system, including a diverse compensation package, constitutes a strong motivational factor for employees, giving the organization a greater chance to achieve its business goals (Zolak Poljašević et al., 2017). Many organizations rely on various incentive pay and benefit package practices to align employee motivation and behaviour with the desired organizational outcomes (Nyberg et al., 2013; Gerhart et al., 2009; Dulebohn & Werling, 2007).

However, in HRM, theory and practice often differ (Timming & Macneil, 2023). There are numerous criticisms that management research is often disconnected from professional practice (Aguinis & Cronin, 2022; Wood & Budhwar, 2021), is highly theoretical, and is methodologically complex. On the other hand, academics (Fletcher et al., 2020; Purcell, 2014; Guest, 2014) criticize practitioners as being 'too often reductionist, normative, and instrumental' (Timming & Macneil, 2023, p.593). This gap between the HRM theory and practice should not be ignored, especially considering contextual influences. Namely, modern principles and the theoretical basis in the HRM field originated in developed Western countries. At the same time, the HRM practice in some other countries significantly deviates from these theoretical postulates. An example is the former socialist countries of Central and Eastern Europe (CEE). Generally, Western human resource management practices in transitional regions are improper due to local institutional and legal systems and a lack of transparency in the often politicized decision-making process (Horwitz, 2011).

In this paper, we aim to explore the dispersion of various forms of incentives in the context of three CEE countries that share a common socialist heritage but which have experienced different levels of alignment with the Western philosophy of management and HRM practices. In this context, three CEE countries were selected as the subject of the analysis: Serbia, Slovenia, Bosnia, and Herzegovina. The main goal of the analysis is to identify the level of use of five different types of incentives in the observed countries and to determine differences among them regarding compensation practices. The data used in the analysis were drawn from the large international CRANET database, which is the result of data collection on HRM practices in over 40 countries worldwide (Zolak Poljašević & Vučenović, 2023; Prince et al., 2020; Farndale et al., 2019; Berber & Slavić, 2018, Berber et

al., 2017). This paper applied descriptive statistical methods, Pearson Chi-Square Test (Franke, Ho & Christie, 2012) and Cramer's V Test (Okeke Charles, 2019), on a sample of 321 companies. Comparative studies of this kind are valuable as they provide an overview of employee reward practices, reveal potential gaps between theory and practice, and point toward desirable directions for developing this field.

The structure of this paper follows the standard IMRAD form. The first section, following the introduction, provides the theoretical background of the research, describing the theoretical significance of employee incentive rewards. The second part describes the CRANET methodology and the research sample. Subsequently, the research results, discussion, and conclusions are presented.

Theoretical Background

Compensation management is a process that aims to reward employees fairly and consistently. Rewarding employees is crucial in an organisation's efforts to gain a competitive advantage, attract and retain human resources, and encourage employee development (Berber et al., 2017). Developing an incentive reward system is a challenge for the management of any organization. For this purpose, companies often use various forms of incentives because the traditional reward system in which salaries play a dominant, and often the only role, faces numerous challenges (Zolak Poljašević et al., 2017; Štangl Šušnjar & Berber, 2014; Ilić et al., 2012).

Incentives represent a significant segment of material rewards. They are determined based on the contribution of an individual or a group of employees to achieve organizational goals. The essence of incentives lies in stimulating work performance by establishing a clear and direct connection between the reward and work results. In practice, various types of incentives are used as strategic tools to encourage employee motivation and satisfaction (Heywood & Wei, 2006), productivity at work (Lazear, 2000), positive attitudes, and work intensification (Ogbonnaya et al., 2017; Vlaev et al., 2019), and organizational commitment (Bayo-Moriones & Larazza-Kintana, 2009). Additionally, incentive pay practices are a good instrument for attracting and retaining employees (Diaz-Fernandez et al., 2013) and for aligning employee and stakeholder interests (Nyberg et al., 2018).

In HRM literature, incentives can be classified in various ways depending on whether they are tied to individual,

group, or organizational performance. Performance-based pay and individual bonuses are most commonly used at the individual level. At the organizational unit or team level, group bonuses are utilized, while at the organizational level, there are organizational bonuses as well as profit or stock sharing, which employers can use in the case of achieving certain organizational-level metrics (Prince et al., 2020). Yang (2019) observes that most organizations use combinations of incentive practices to address different goals and balance pay with performance. For the purposes of this research, five types of incentives were analysed: performance-related pay, bonuses based on individual goals, bonuses based on team goals, bonuses based on organizational goals, and non-monetary incentives.

Usually, companies from different countries adopt different combinations of incentive practices because incentives are context-dependent. Many factors, such as national regulations, the state of the labour market, social and political trends, and economic development, influence the preferred combination of incentives at the country level. Numerous studies indicate the influence of national culture on preferred incentive practices in different countries (Prince et al., 2016; Prince et al., 2018; Prince et al., 2020). Hofstede's cultural dimensions - power distance, individualism, masculinity, and uncertainty avoidance (Hofstede, 1984) - are also linked to preferred forms of employee reward (Gooderham et al., 2018; Frank et al., 2015). This study will analyze the dispersion of different forms of incentives in three CEE countries that share a common socialist heritage, namely Slovenia, Serbia, Bosnia, and Herzegovina. During the socialist period, the reward system in CEE countries was characterized by several key features, such as 'centrally planned wages, significant variable payments, and a wide variety of benefits' (Berber et al. 2017, p. 1665). Today, this region cannot be seen as a homogeneous entity, and the reward practices in these countries cannot be viewed as a uniform model. Therefore, this study starts with the following hypotheses:

H1: A statistically significant difference exists in performance-related pay use among observed countries, regardless of their common socialist heritage.

H2: There is a statistically significant difference in the use of bonus on individual, team, and organization level among observed countries, regardless of their common socialist heritage.

H3: There is a statistically significant difference in the use of non-monetary incentives among observed countries, regardless of their common socialist heritage.

The defined hypotheses were tested using the appropriate statistical analysis according to the presented methodology.

Methodology and Sample

We used data from the latest CRANET research from 2021 to investigate the compensation systems in the selected countries. CRANET research is conducted cyclically for several years to gather a representative sample across multiple countries. CRANET research is conducted according to the same methodology in 40 countries of the world to enable comparison of data on HRM practices. It is designed to draw representative samples from each country (Steinmetz et al., 2011; Cited in Prince et al., 2020). Despite certain methodological limitations, CRANET research is very important because it has provided continuous empirical data on developing HRM practices in member countries for three decades. The questionnaire comprises closed-ended questions, meaning respondents were expected to choose from the provided options. The questionnaire was filled out by HR managers in organizations employing more than 100 employees. In this research, a total of 321 companies from Slovenia, Serbia, Bosnia, and Herzegovina were examined.

Table 1

Sample structure per countries

	Frequency	Percent
Bosnia and Herzegovina	47	14.6
Serbia	106	33.0
Slovenia	168	52.3
Total	321	100.0

Source: Authors based on CRANET 2021 database

As shown in Table 1 most companies operate in the service sector, about 70%, while the rest (30%) are in the manufacturing sector. About 60% work in the private sector and 40% are in the public sector.

In CRANET methodology, each incentive scale is composed of binary items (1 = yes, 0 = no). Respondents were expected to indicate whether they use the observed incentives separately for four categories of employees: managers, technical/professional, clerical, and manual staff. In this paper, only two categories of employees were observed: managers and technical/professional staff. The analysis was conducted in two phases. In the first phase, a descriptive analysis

was performed to assess the level of use of different incentive pay practices in the observed countries. In the second phase, the Pearson Chi-Square Test (Franke, Ho & Christie, 2012) and Cramer's V coefficient of association (Okeke Charles, 2019) were applied to test the hypotheses, i.e., to determine statistical differences in the level of application of three different forms of incentives among the observed countries, including pay for performance (H1), bonus (H2) and non-monetary incentives (H3). Research data were analyzed using SPSS software.

Results

The data analysis in this study begins with descriptive statistics, aiming to illustrate the prevalence of various forms of employee incentives in the observed companies. The results are presented separately for each country and according to two basic categories of employees: managers and professionals.

According to the data in Table 2 there is evidence that bonus based on individual goals is mostly used in all

Table 2

The percentages of the companies that use different incentive pay practices

	Performance related pay	Bonus based on individual goals	Bonus based on team goals	Bonus based on organizational goals	Non-monetary incentives
Managers					
Bosnia and Herzegovina	34.0%	46.8%	21.3%	23.4%	34.0%
Serbia	69.8%	72.6%	53.8%	63.2%	53.8%

Source: Authors based on CRANET 2021 database

countries for both groups of employees (53.6% and 52.6%, respectively), accompanied by performance related pay (48.6% and 50.5%, respectively). In managers

and professionals' case, the smallest percentage of companies offers bonus based on team goals (29.3% and 29.9%, respectively).

As shown in Table 2, companies in Bosnia and Herzegovina mostly use individual bonuses (46.8% of companies) for managers and professionals. Besides individual bonus there is performance related pay (40.4% in both cases). In Serbia, for managers, companies mostly use individual bonuses (72.6% of companies), and for professionals, performance-related pay (69.8%). In Slovenia, for managers and professionals, companies mostly use individual bonuses (43.5% and 47% of companies, respectively).

For hypotheses testing, the Pearson Chi-Square Test and Cramer's V Test of the strength of association were utilized, and the results are presented below in Tables 3-5.

As shown in Table 3, there is statistically significant association between the use of Performance-related pay for managers and the company's country of origin ($p < 0.001$). Also there is a statistically significant association

between the use of Performance-related pay for professionals and country of origin of the company ($p < 0.001$). The Cramer's V test of the strength of association shows that the strength of association between the variables is 0.213 ($p < 0.001$) for managers and it is 0.272 ($p < 0.001$) for professionals, which are moderate associations (Table 3) (Pallant, 2009, 221). We can see that Bosnia and Herzegovina shows the smallest percentage of companies that offer this kind of rewards to their employees, and those companies in Serbia use performance-related pay more than other countries, for both groups of employees.

The results of the Pearson Chi-Square Test and Cramer's V Test provide sufficient evidence to confirm the first hypothesis (H1), which states that there is a statistically significant difference in the use of bonus on individual, team, and organization level among observed countries, regardless of their common socialist heritage.

Source: Authors based on CRANET 2021 database

In the case of bonus based on individual goals, there is a statistically significant association between the use of bonus based on individual goals for managers and the company's country of origin ($p < 0.001$). Results shown in Table 4 indicate the same results for professionals and the company's country of origin ($p < 0.001$). These results are shown in Table 4. The Cramer's V test of the strength of association indicates that the strength of association between the variables is 0.269 ($p < 0.001$) for managers and 0.206 ($p < 0.001$) for professionals, which are moderate associations (Table 4). We can see that Bosnia and Herzegovina shows the smallest percentage of companies that offer this kind of reward to their employees and that companies in Serbia use this kind of compensation more than other countries for both groups of employees.

In the case of bonus based on team goals, Table 4 presents a statistically significant association between the use of bonus based on team goals for managers and the company's country of origin ($p < 0.001$). Also there is a statistically significant association between the use of Bonus based on team goals for professionals and the country of origin of the company ($p < 0.001$). The Cramer's V test of the strength of association shows that the strength of association between the variables is 0.380 ($p < 0.000$) for managers and 0.395 ($p < 0.001$) for professionals, which are moderate associations. We can see that companies from Slovenia show the smallest percentage of offering this kind of rewards to their employees, and those companies in Serbia use this kind of compensations more than other countries, for both groups of employees.

In the case of bonus based on organisational goals, there is a statistically significant association between the use of bonus based on organizational goals for managers and country of origin of the company ($p < 0.001$). Also there is a statistically significant association between the use of Bonus based on organizational goals for

professionals and country of origin of the company ($p < 0.001$). The Cramer's V test of the strength of association shows that the strength of association between the variables is 0.306 ($p < 0.001$) for managers, and it is 0.263 ($p < 0.001$) for professionals, which are moderate associations. We can see that Bosnia and Herzegovina shows the smallest percentage of companies that offer this kind of rewards to their employees and that companies in Serbia use this kind of compensations more than other countries, for both groups of employees.

The presented results confirm the second hypothesis (H2), which states a statistically significant difference in the use of performance-related pay among the observed countries, regardless of their common socialist heritage.

In the case of Non-monetary benefits, data in the Table 5 shows that there is a statistically significant association between the use of non-monetary benefits for managers and country of origin of the company $p < 0.001$, but not for professionals and country of origin of the company ($p > 0.005$). The Cramer's V test of the strength of association shows that the strength of association between the variables is 0.210 ($p < 0.001$) for managers, which is moderate. These results are shown in Table 5. We can see that Slovenia shows the smallest percentage of companies that offer this kind of rewards to their employees and that companies in Serbia use this kind of compensation more than other countries, for both groups of employees.

The results of the Pearson Chi-Square Test and Cramer's V Test provide sufficient evidence to confirm only one segment of the third hypothesis (H3) related to managers as an observed category of employees. Regarding professional/technical staff, the analysis results indicate no statistically significant difference in using non-monetary incentives among the observed countries. Therefore, the third hypothesis is partially confirmed.

Table 5

Pearson Chi-Square Test and Cramer's V test for non-monetary incentives

Discussion and Conclusions

Rewarding employees undoubtedly represents one of the most important and complex human resource management activities, regardless of whether viewed from the perspective of the employer or the employee. For employees, the amount and structure of rewards directly affect the ability to maintain a satisfactory standard of living. From the employer's perspective, establishing a stimulating reward system helps the organization to attract, motivate, and retain quality human resources and achieve defined goals.

HRM theory assumes that a more complex reward system based on various incentive pay practices and benefits packages gives the organization a greater chance of achieving the desired organizational outcomes. However, in this field, theory and practice often differ (Timming & Macneil, 2023; Aguinis & Cronin, 2022; Wood & Budhwar, 2021), especially in less developed regions or countries. An example of the gap between theory and practice can be found in former socialist countries in CEE, assuming that this region cannot be considered a homogeneous entity despite their common socialist heritage.

This research provides evidence that companies from three observed CEE countries use all five forms of stimulation, which were selected as the subject of analysis in this research. As expected, the degree of use of certain incentive pay practices varies among the observed countries. However, regarding rewarding managers, the research results indicate that all three observed countries mostly use individual bonuses. Such results are consistent with similar studies conducted in

other countries (Kulak & Atay, 2020). For rewarding professionals in Serbia, Bosnia, and Herzegovina, most companies apply performance-related pay, while in Slovenia, individual bonuses are the most prevalent for this category of employees. Therefore, the practical implications of the paper lie in the fact that HR professionals responsible for an organization's compensation and benefits should carefully consider elements of their motivational package having in mind that most companies in selected countries use performance-related pay and individual bonuses. Tailoring compensation package for employees needs to include these two types of rewards beside basic pay and benefits. Pay for performance and bonuses are directly related to employees' performances, and those are seen as drivers of employees' productive behaviour. Neglecting monetary incentives could harm employees' attitudes and even behaviour, producing poor performance, which is a sensitive theme in today's unpredictable business environment, in which human resources are recognized as a driver of sustained competitive advantage.

Hypotheses testing were performed using Pearson Chi-Square Test and Cramer's V Test. Testing was done separately for three categories of incentives (pay for performance - H1, different level bonuses - H2, and non-monetary incentives - H3) and for two categories of employees (managers and technical/professional staff). In the first category of employees, the results indicate a statistical difference in applying all incentive elements among the observed countries. For professional/technical staff, this difference is shown for all incentive elements except for non-monetary incentives. Therefore, H1 and H2 are fully confirmed,

while H3 is only partially confirmed. Such results contribute to understanding the specific country context when designing incentive systems and support a divergent approach based on the hypothesis that institutional and cultural differences among countries cause national differences in human resource management practices. The paradigm of divergence is quite prevalent in Europe, as supported by the results of this research and numerous other similar studies (Berber et al., 2017; Prince et al., 2016; Prince et al., 2018; Prince et al., 2020; Drury, 2016). According to one of the CRANET reports (2011), differences in compensation elements are “based on cultural differences in the acceptance of those forms of variable pay as well as differences in business regimes” (Berber et al., 2017).

While CRANET research has numerous advantages arising from the fact that data on HRM practices are collected in more than 40 countries using the same methodology, its limitations also stem from there. Research of this kind provides the opportunity to

compare practices among countries worldwide and over time, as the research is repeated every few years. On the other hand, it does not allow more profound analysis of the observed human resource management practices, which is conditioned by the relatively simple form of the CRANET questionnaire with closed-ended questions and the principle of a single respondent per company. Specifically, in the case of incentive practices, this research allows us to observe the frequency of using certain forms of incentives in practice, but it does not answer why this is the case. The limitation in this study is also reflected in the use of simple statistical techniques to observe differences among countries. Regarding further research, CRANET provides excellent opportunities for comparative studies of different HRM practices and the field's current state. Still, more profound research that would explain the motivation and processes that have led to the current state in the field of HRM would also be helpful.

Od teorije do prakse: spodbude za menedžerje in strokovnjake

Izvleček

Čeprav je v teoriji precej literature, ki poudarja pomen spodbudnih plačil zaposlenih, ni veliko empiričnih raziskav, ki bi pokazale njihovo razpršenost v praksi. Osnovni namen te študije je raziskati raven izvajanja različnih spodbud v treh državah: Sloveniji, Srbiji ter Bosni in Hercegovini. Raziskava je bila izvedena na vzorcu 321 podjetij. Podatki za to študijo so bili pridobljeni iz podatkovne zbirke CRANET. Zadnji cikel zbiranja podatkov je bil izveden v letih 2021-2022. Poleg opisne statistike sta bila za preverjanje hipotez uporabljena Pearsonov test Chi-Square in Cramerjev test V. Rezultati raziskave kažejo na statistično pomembno razliko v uporabi večine opazovanih elementov nadomestil med opazovanimi državami. Študija prispeva k literaturi o upravljanju nadomestil, saj predstavlja empirične podatke o stopnji izvajanja različnih instrumentov nadomestil v treh opazovanih državah.

Ključne besede: spodbude, nadomestila, kontekst države, vodstveni delavci, strokovnjaki
